PAPER NO. 85-5043

THE EDUCATION AND UTILIZATION OF AGRICULTURAL ENGINEERS IN THE DEVELOPMENT OF INDONESIA

By

Eriyatno

Dept. of Agro-Industry Technology
Bogor Agricultural University
Indonesia

For Presentation at the 1985 Summer Meeting
AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS

Michigan State University, East Lansing
June 23 - 26, 1985

SUMMARY:

The role of AE graduates in Indonesia will increase in line with national programs on food, alternate energy, waste product utilization, soil conservation, industrial pollution control, computer application and biotechnology.

THE EDUCATION AND UTILIZATION OF AGRICULTURAL ENGINEERS IN THE DEVELOPMENT OF INDONESIA [1]

By

Eriyatno [2]

BACKGROUND

Modern agriculture in the developing countries requires dynamic farmers who can quickly interpret the developmental technology and the demand for agrocommodities. Undoubtedly, investment in information and knowledge is a fundamental source of productivity growth and social welfare. Education speed up the process of technological diffusion, especially in the case of agriculture. In this context, strong linkage can be observed between education and utilization of agricultural engineers. This linkage is detected by the increasing role of agricultural engineering in the development of Indonesia.

Despite encouraging progress in petroleum export and industrial activity, the mainstay of Indonesia economy in the foreseeable future will be agricultural sector. Thirty percents of the Gross Domestic Product and one thids of the export earnings are derived from agriculture. It is estimated that agriculture employs over 60 percents of the urban households. In order to achieve the projected economic growth rate of 6.5 percent per year, agricultural production is required to increase at 3.5 percent annual rate.

---

[1] Prepared for presentation at the ASAE Summer meeting, June 1985

[2] Department of Agro-Industrial Technology, Bogor Agric. Univ., Indonesia

To meet the projected consumption requirements of 150 million population, with a rapid growth of 2.3 percent per year and stimulated by rising agregrate income, it is estimated that food production must be doubled in just 17 years. Furthermore, in lime to get more foreing currency earnings, industrial crops, fishery and forestry production should generate sufficient additions to non oil export revenue. These are basic challenges faced by agricultural engineers now and in the years to come.

RECENT DEVELOPMENT OF AGRICULTURAL TECHNOLOGY

The agriculture in Indonesia is diverse. However, within the diversity there are several characteristics which are generally typical for smallholders activity across the islands.

(1) holdings are generally small

3.00 ha	:	5.6 percent
0.75 - 3.00 ha	:	32.9 percent
0.30 - 0.75 ha	:	32.9 percent
0.30 ha	:	28.6 percent

(2) most farm activity is devoted to food crops production (86.6 %) and only about 12 percent have mixed crop/livestock or poultry production.

(3) the area of irrigated farming is 34.2 % of total crop acreage. Little of this irrigation is classified as technical (13.56 %) and semi-technical (13.74 %).

(4) there is relatively low use of fertilizer and pesticides. Only 37.8 % apply chemical fertilizer, 12.6 % farm manure and 6.8 % combination of both. The average amount of chemical fertilizer applied is 170 kg/ha.

(5) most of the power supplied by manual labor, even-though the land cultivation cost with a tractor is 60 US $/ha compare with 70 US $/ha for manual labor.

(6) only around 30 % of farmers live in moderate condition. Most of them have weak purchasing power for industrial goods. Each harvest of rice the average net income is just about 200 US $/ha.

Considering those conditions the technological improvement introduced by agricultural engineers has had difficulties and lots of failures have occured in mechanized projects. However to some extent, the advance of agricultural technology has improved significantly, particularly in post harvest activities and irrigation pumps. Table 1 shows the current and projected need for agricultural implements and machineries.

Table 1. Agricultural Equipments and Machineries in Indonesia *)

Specification	1984	1985	1986	1987	1988
Tractor	19200	23040	27640	33200	39840
Sprayer	63000	72000	83300	95800	110280

Reaper	1290	2077	2780	4179	5546

*) Department of Agriculture, GOI , 1984

The implementation of agricultural technology is relevant to the national strategy of agricultural development These are :

(1) intensification, an increase of productivity through utilization of appropriate technology which still considers the conservation of energy, natural resources and the environment.

(2) extensification, which includes the expansion of new agriculture areas by using arable land related to the new settlement and transmigration efforts.

(3) diversification, a variety of farming system to produce various commodities in line with local resource potential and market demand.

To support the technological adaption and transfer on these programs, agro-based industry must also improved. The main industries are product processing plants, and equipment and machineries manufacturing plants. Table 2 shows the production capacity of agricultural equipment manufacturing industries in 1984.

Table 2. Production Capacity of Agricultural Equipment Manufacturing Industry in Indonesia, 1984 *)

Specification	Production Capacity per Year			Total Company
	Licensed	Potential	Actual	
Hand hoes	1 072 000	950 060	530 036	4
Hand Tractor	27 660	6 088	2 361	13
Mini-tractor (4-wheel)	3 100	1 700	50	3

EDUCATION OF AGRICULTURAL ENGINEER

Higher learning institutions of agricultural engineer in Indonesia were started formally in 1963 at the Faculty of Agricultural Technology, University og Gajah Mada (UGM). In 1964, a similar faculty was formed in the Bogor Agriculture University (IPB). Before then, agricultural mechanization was only part of the crop science curricullum in the Faculty of Agriculture. Through a US-AID program, a Kentucky University consultant had been retained to accelerate the AE education program in both universities. Members of the teaching staff were trained in US. In the beginning of 1970, the MUCIA - AID program begun and contributed much to the AE Department of IPB and UGM. Long term and short term experts were assigned to develop appropiate curriculum. The contribution of Prof. Stout and Prof. Esmay has been recognized by both universities. The concept of selective mechanization was introduced and has expanded.

The growth of AE department quantity and quality wise, begun to accelerate faster as several staff members came back from US with advanced degrees. Other universities have also started AE curriculums. These include the University of Hasanuddin in South-Sulawesi, the University of Andalas in West Sumatra and the University of Brawijaya in Malang. IPB and UGM have produced graduates since 1970, and at present there are about 700 agricultural engineers. This amount is far from enough for the agricultural technology manpower requirement in Indonesia. The student body in the AE department in IPB is around 300 and in UGM it is around 250.

In the early years the AE curriculum at IPB had been estimated to have only 35 percent engineering courses, but today there are around 86 percent that are considered as engineering science. (see App. 1 for the recent curriculum)

The specialization fields covered by AE Department are:

(1) Farm machinery and equipment
(2) Soil and water engineering
(3) Agricultural hydrology and irrigation
(4) System and management for agricultural mechanization
(5) Food and agricultural products processing
(6) Energy and rural electrification
(7) Environment and farm structure

In 1981, the Faculty of Agricultural Technology at IPB founded a new department in order to provide professionals needed for the fast growth of the agro-industry in Indonesia. At present, the Department of Agro-Industrial Technology (AIT) has already produced more than 40 graduates working in various field of the agro-based industry. (see App. 2 for AIT curriculum). This department covered 3 main specializations:

(1) industrial engineering and management
(2) agro-chemical engineering
(3) bio-technology/bio-industry

The AIT Department also has a quality control and packaging laboratory. During 1984, UGM began to set up a similar department.

The demand for the AIT graduates is increasing. Mostly this comes from the estate crops processing industry. Computer application has been the main thrust in the AIT department. It is extensively used for management science and operation research courses. Software technology has begun to be appreciated in agriculture bussiness.

Graduate study for AE was started at IPB in early 1980, both in Master and Doctor program. The curriculum of AE graduate programs is attached in Appendix 3. With aid

from Japan International Cooperation Agency (JICA), the graduate program at the Faculty of Agricultural Technology is growing fast. A new building has been erected and technical assistance for a 3 years program has been planned. The in-country graduate program will enable Indonesia students to select their research or dissertation studies relevant to the current problem in agricultural technology.

UTILIZATION OF AGRICULTURAL ENGINEER

The number of Indonesian researcher and scientist invol ve in agriculture problem are relatively small. In 1975 there were only 900 researchers to fill a total need of 18,500 for the same year. This shortage should be solved immediately to prepare the even more challenging problem on food, energy, environment and population explosion issues. To cope with human resources development, the state universities of Indonesia has been stressed to increase their student body by to 10 to 15 percents per year. Budged constrainsts make this effort very difficult to achieve.

To gain an overall view of the utilization of AE graduates is not easy since there is no fixed record of their employment. Table 3 shows the AE alumni of IPB to the year of 1979, concerning their occupation distribution.

This table shows that about 21 percent at the graduates are working in University and around 22.5 percent work in the private sector. More than 65 percent work in various governmental agencies. It is expected that the private sector will utilize more in the future. The small sumbers that work in the private sector in due to limited growth of mechanization for small farming system and current slow investment in agro-business. Most of them work as sales engineers for big

international companies, but very few works in local manufacturing industry or private mechanization projects.

In 1967, the first symposium of Agricultural Mechanization was held in Bogor. On August 10, 1968 the Indonesian Society for Agricultural Engineer (PERMETA) was established. This professional organization has conducted several seminars, technical meeting and conference to discuss the national issues in agricultural technology application. Its members include scientists, university staff, factory managers, field practioners, research workers, government representatives and students.

Tabel 3. AE Alumni of IPB, Occupation Distribution

Year	Higher Learning Institute	Research Bodies	Government Agencies	Government Owned Company	Private Sector	Other *)
1970	0	2	0	0	0	0

Total	26	19	20	21	21	7

*) Bank, Cooperatives, Consultants etc.

FUTURE TRENDS

In the Indonesia National development strategy, it is stated that higher learning institution should increase their role as the center for science and technology development as well as the center for developmental research related to national goals. Therefore, they should improve their productivity, creativity, quality and work efficiency. In this decade, most agro-complex universities in Indonesian are in the phase of improvement to their physical facilities and human resources. There is a great deal of international aid involved in this program. Since they are still in the process of institutional building, their production evaluated as still inadequate to meet the national demand of alumni and technological progress.

In the field of Agricultural Technology, there are several factors that could accelerate the growth of the AE profession. These factors can be identified as :

(1) Food Availability. Intensification of farm land is not enough to supply food adequately since the yield per hectare is reaching its optimal value. Therefore, extensification which requires the use of heavy machineries is intended to supplement the production efforts.

(2) Alternative Energy. Fuel in rural areas is expensive and not feasible for various commodities processing factories. Green energy, such as gasohol from cassava starch, is increasing as well as wind, water and solar energy for farming usaged. However, further research still has to be done to improve the efficiency.

(3) Waste Product Utilization. More than 70 % by weight of agricultural plants are wasted. The new process of waste utilization could add to farmers income considerably, i. e. paddy stalk, cocconut shell, sugar cane tops etc.

(4) Soil Conservation. The environmental is a big issue nowadays for marginal land. Erosion control through better drainage and land development pattern is needed in many parts of the country.

(5) Industrial pollution Control. Some of the agro-process industry produce pollutant, such as cassava starch factories. There should be technological efforts to reduce the negative impact to the living environment especially in the rural areas.

(6) Computer Application. Management is one of the weakest part of the agro-business, from traditional farming to large scale estate crop plantations. Computer application combined with software technology could assist in developing management information and decision support systems. It will increase planning and evaluation efficiency and effectiveness in governmental agencies and private industries.

(7) Bio-technology. The use of micro-organism in producing foodstuff has been known since quite long ago (i. e. tempeh, soy bean sauce etc.). The advancement of bio-technology is a future challenges that can provide new horizon for agricultural engineers.

In spite of many accelerated factors, the AE educational system still is confronted with difficulties in its professional development. The lack of educational facilities, especially in hardware training, produce not-so-ready graduates. Beside, the agro socio-economic condition in Indonesia, where smallholders is dominant, makes technological innovation and dissemination quite difficult. But there is no doubt that AE graduates role in national development will be expected to increase. International cooperation on research and development is necesarry to support this development with aim to building a better world.
