

**PRODUKSI LISTRIK DAN HUMOTEKS DARI LIMBAH PADAT
KELAPA SAWIT DENGAN PROSES DRANCO ¹⁾**

**PRODUCTION OF ELECTRICITY AND HUMOTEX FROM OIL PALM
SOLID WASTES THROUGH DRANCO PROCESS**

R. Sudradjat²⁾

RINGKASAN

Dranco proses (Dry Anaerobis Conversion) adalah proses fermentasi anaerobic yang dapat mengubah bahan organik menjadi biogas (listrik) dan humotex (kompos anaerobik). Penelitian ini mempelajari aspek teknis dan ekonomis pemanfaatan limbah perkebunan kelapa sawit berupa tandan dan kulit buah menggunakan model perkebunan sawit seluas 2000 ha.

Dari areal tersebut akan dihasilkan 38 ton tandan basah perhari atau 52 ton substrat pada 28% KK (kadar kering). Melalui proses Dranco, substrat tersebut akan diubah menjadi biogas dengan kapasitas 2700 m³ CH₄ (methane) atau 7881 kwh tenaga listrik dengan netto sebesar 6881 kwh perhari. Humotex yang dihasilkan adalah 8 ton pada 90% KK.

Analisis ekonomis menunjukkan Net Present Worth Rp. 1184 juta, B/C rasio 1.83 Internal Rate of Return 41.2%. BEP untuk produksi tenaga listrik terletak pada 883 kwh dan humotex 104 ton perhari. Proyek ini secara teknis dan ekonomis beralasan untuk dikembangkan.

I. OIL PALM IN INDONESIA

Indonesia is greatly dependent on oil for its foreign currency. This situation leads to enhancement of the production and export of non oil commodities especially agricultural products. In this respect, oil palm is an important product in the agricultural sector.

¹⁾ Disampaikan pada Seminar Bioteknologi Perkebunan dan Lokakarya Bopolimer Untuk Industri PAU Bioteknologi IPB, Bogor, 10 - 11 Desember 1991.

²⁾ Pusat Litbang Hasil Hutan, Bogor.

It has been increasing its acreage throughout many provinces in Indonesia.

In 1983, oil palm plantations in Indonesia covered 440.766 ha which 273.035 ha of mature trees and 167.731 ha of immature trees. In the 1983-1988 period, palm estates are expected to expand at an average rate of 8% year, whereas oil palm and kernel production is expected to increase by an average of 15.7 and 15.9% respectively. In 1989, Indonesia's oil palm plantation is 980.693 ha, about a half of the average are in the production age. Oil palm production in 1989 is about 2 million ton.

Currently, wastes such as Empty Fruit Bunch (EFB) and Pericarp (P) are burnt in the factory and thus recycled in the form of heat and mineral fertilizers. Since FEB and P have high moisture content, they need preheating (sundrying) or mixing with another type of dried biomass to be able to be used as type for boilers. In order to get energy to high value from such wet materials, the possible application of biogas technology deserves to be evaluated.

In the processing of oil palm, several types of organic wastes are produced. The treatment of waste water has received a lot of attention (Petitpierre, 1982; Martin, 1981). By anaerobic digestion the COD and BOD of oil palm factory effluents can be lowered 75 - 95% and substantial amounts of biogas concomitantly produced. Furthermore, the digested effluents can be recycled as a non phytotoxic soil fertilizer (Lim Kim Huan, 1986).

This study focusses on the conversion of EFB and P by means of a special type of biogas fermentation, the so called Dranco Process (Dry Anaerobic Conversion).

II. TECHNICAL ASPECTS

A. Available substrates

This study was applied to a 2000 ha oil palm plantation.

1. Fresh Fruit Bunch (FFB) = 20 ton green matter/ha yr (25% DM). For 2000 ha = 40.000 ton green matter/yr or about 100 ton green matter/d.
2. Waste products.
Empty Fruit Brunch (EFB) 38% of FEB = 38 ton green EFB/d (25% DM) Or 9.5 ton DM/d. Pericarp (P) 9% of FEB = 9 ton wet weight/d (55% DM) or 4.9 ton DM/d. After steaming during oil palm processing, the dry matter content decrease to 35%. Hence, one has $5.0/0.35 = 14.0$ ton wet waste perday.
3. Total available substrates (EFB + P): $38 + 14.0 = 52.0$ ton/d at 28% DM ($14.5/52.1$) or 14.5 ton DM.

B. Operational parameters

1. Process

Nama of the process	: Dranco Process
Temperature	: 55°C
Substrate dry matter	: 28%
Volumetric loading	: 12.5 kg DM/m ³ r.d. rate
Retention time	: 22.5 days
Conversion to organic	: 40% of COD is considered to be converted to methane gas. This figure is based on laboratory tests.

Table 1. Material composition of the fermentor

Tabel 1. Komposisi material dari fermentor

Compositon (Komposisi)	Thickness (m) (Ketebalan)	(W/m.k)
Coating (inner side) (Lapis dalam)	0.003	0.17
Cement plaster (Plester semen)	0.05	1.5
Reinforced concrete (Beton)	0.19	1.9
Cement plaster (Plester semen)	0.01	1.5
Extruded polystyrene (Plastik polistirene)	0.06	0.035
Cement plester (outer side) (Semen lapis luar)	0.01	1.5

2. Construction and wall compositions of the fermentor.

Per day 52.1 ton substrate at 28% DM (14.5 ton DM) will be digested at loading rate 12.5 kg DM/m³ r.d. Hence this substrate will be fed in a fermentor of $14.500/12.5 = 1160 \text{ m}^3$. In practice 1400 m³ is required. It is proposed to built a circular vessel with $r = 5 \text{ m}$ and $h = 17.9 \text{ m}$. The wall of fermentor is composed with several different materials from the inner side to outer side which are respectively shown in table 1. These material composition cover the whole body of the fermentor. It is however conceivable to construct the digester in a more simplified way because, as will be shown further on the heat balance of the process is not critical.

3. The inhouse power concumptions.

The inhouse power consumptions of the Dranco Process shown in table 2. These values are based on information obatined from De Wilde and Van Hile (1986).

Table 2. The inhouse power consumption

Tabel 2. Tenaga yanag dikonsumsi sendiri

Items	Consumption (Konsumsi)	Amount (t/d) (Jumlah)	Kwh/d
Chopper (Pencacah)	4.0 kwh/ton	55	220
Conveying and mixing (Penghantar dan Pengaduk)	3.0 kwh/ton	200	600
Water pupm (Pompa air)	0.5 kwh/ton	20	10
Press machine (Mesin pres)	4.0 kwh/ton	32	128
Siever (Penyaring)	4.0 kwh/ton	10	42

C. Production of biogas and elctricity

1. Production of biogas.

The daily methane prodcuton will be : 14.5 ton DM/d x 4.4 x 1.33 x 350 m³ CH₄ = 2700 m³ CH₄, equal to 2700 m³ x 100/60 = 4500 m³ biogas.

2. Thermal energy needs for the Dranco Proces.

* Energy needs for heating up the need:

52100 kg/d x (35°) x 1 kcal/kg°C x 4.18 MJ/kcal x 10³ = 7622 MJ/d.

- * Energy needs for maintaining temperature at 55°C, are calculated based on the formula:

$$Q = \Sigma KA \dot{v} t, \text{ from which : } k \frac{1}{1/\alpha_i + \Sigma d/\lambda + 1/\alpha_u}$$

The calculation gives : $\Sigma k = 0.53 \text{ W/m}^2 \text{ }^\circ\text{K}$ for $\alpha_i = 600 \text{ W/m}^2$ and $\alpha_u = 25 \text{ W/m}^2$. Since the fermentor has a size of $r = 5 \text{ m}$ and $h = 17.9 \text{ m}$ then $A = (2 \pi 5 \times 17.9 \text{ m}) + 2(78.5) = 719.1 \text{ m}^2$

Maintaining the temperature will roughly require $= 0.63 \times 719.1 \times (55 - 20) \times 10^{-3} \times 3.6 \text{ kJ/W} \times 24 = 1152 \text{ MJ/d}$. When the wall is simplified with coating, cement plaster and reinforced concrete ($d = 0.24 \text{ m}$), the heat required to keep the reactor on temperature is 9512 MJ/d.

- * Energy for drying 13 ton humotex, 70% DM to become 10 ton 90% DM = $3000 \times (100 - 30) \text{ kcal/kg}^\circ\text{C} = 877.8 \text{ MJ}$
 $3000 \times (100 - 30) \text{ kcal/kg}^\circ\text{C} = 877.8 \text{ MJ}$
 $3000 \times 540 \times 10 \times 4.18 = 6771.6 \text{ MJ}$

 7649.4 MJ

- * Total thermal energy need for Dranco process:
 $762 + 9512 + 7649 = 24783 \text{ MJ/d}$

3. Energy balance of the Dranco process.

About 50% of the biogas thermal energy can be recuperated from generator and 60% from it will be lost during heat transfer. Total thermal energy from biogas is $2700 \text{ m}^3 \text{ CH}_4 \times 35 \text{ MJ/m}^3 \text{ CH}_4 = 94500 \text{ MJ/d}$. Recuperated thermal energy is $0.5 \times 94500 \times 0.6 = 28350 \text{ MJ/d}$. Total thermal energy needs amount in the worst case is 24783 MJ/d. Thus, all the thermal energy needs for Dranco can be obtained from excess heat, produced by generator.

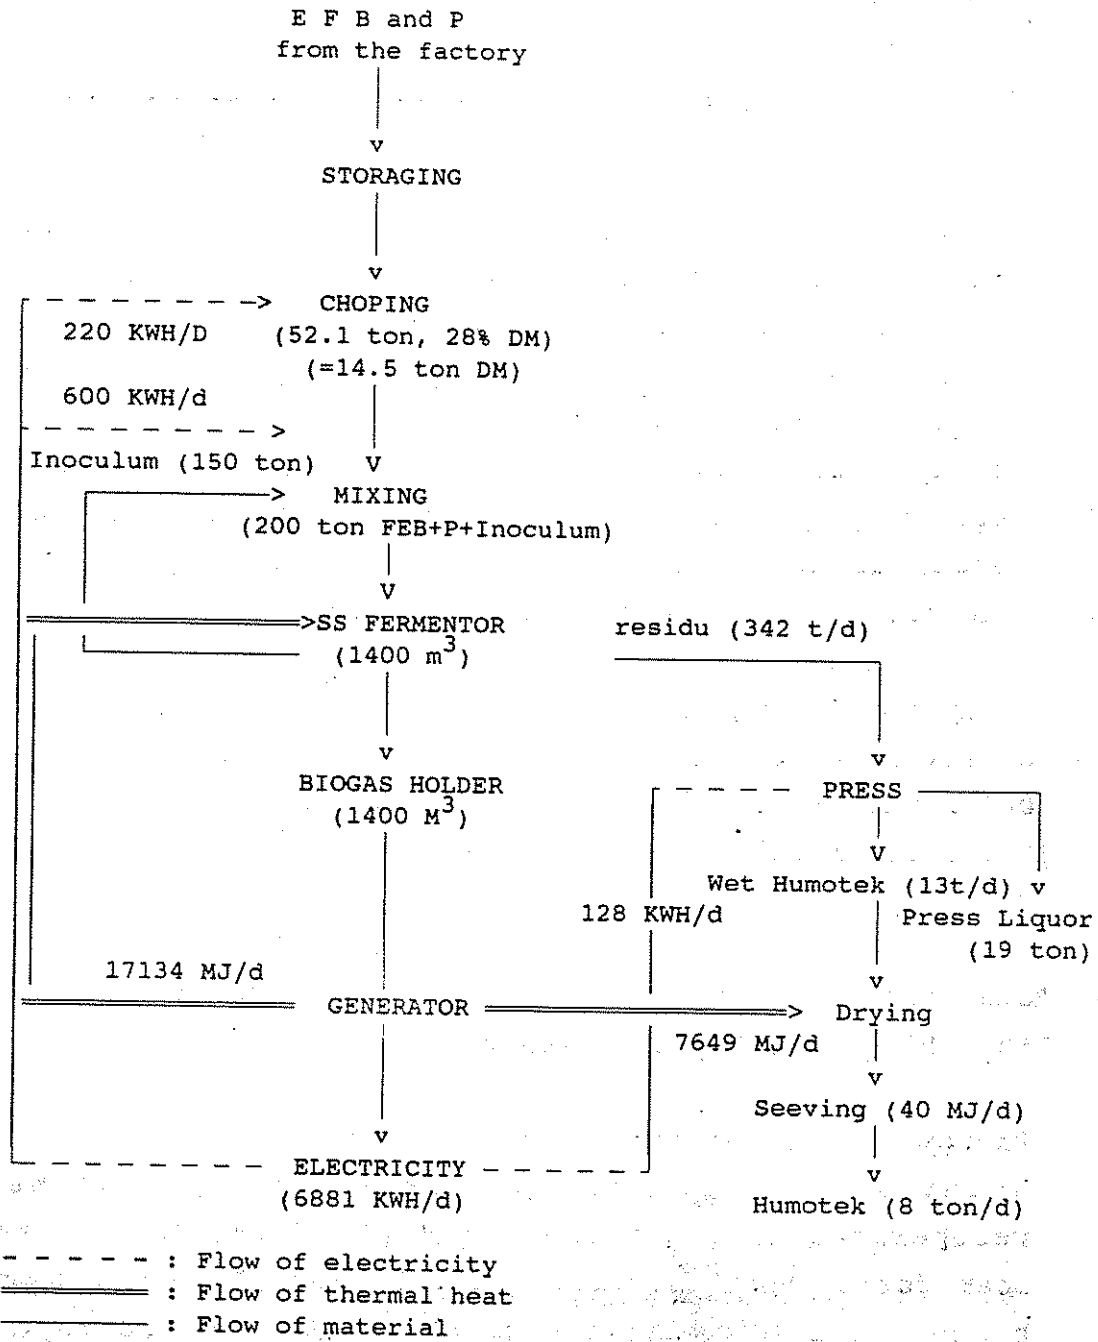

Figure 1. Process and materials lay out
 Gambar 1. Diagram alir proses dan material

4. Electricity and humotex production.

* Electricity production.

Gross electricity production from the biogas is :
 $94500 \text{ MJ/d} \times 0.278 \text{ kwh/MJ} \times 0.3 = 7881 \text{ kwh/d}$. In view of the electricity required by the Dranco is self (see Table 3), the net electricity production will be : $7881 \text{ kwh/d} - 1000 \text{ kwh/d} = 6881 \text{ kwh/d}$. The generator capacity required at a load factor 0.6 is $7881 \times 1/15^{*}) \times 1/0.6 = 875 \text{ kw}$ or 900 kwh.

* Humotex production

After fermentation about 40% of the COD will be reduced to methane, or $14.5 \text{ ton} \times 1.33 = 7.7 \text{ ton}$. The residu after fermentation will be about 14.5 (1.33). $0.6 = 12 \text{ ton COD}$ or ca. 9 ton DM after pressing, the dry matter content of the humotex will be 65% or the wight of humotex will be $9/0.65 = 32 \text{ ton}$ at 28% DM. By pressing, the moisture is reduced and get 13 ton of 70% DM. The energy required for drying is 7649 MJ/d to get 10 ton of 90% DM. After seeving, the humotex obtained is 8 ton at 90% DM.

III. ECONOMICAL ASPECT

A. Investment

Table 3 shows the investment of the Solid State Fermentation Project at 4500 m^3 biogas production capacity. All the biogas is converted to electricity and heat. The values between bracket indicates the cost price in million rupiah per unit. The investment needs for this project roughly estimated at 1450 million rupiah.

Of which:

*) 15 hours operation/day

- Constructional parts (+) : 784 million, life time 20 years.
- Mechanical parts (-) : 622 million, life time 10 years.
- Special part (++) : 80 million, life time 5 years R

B. Depreciation

1. Depreciation of mechanical parts.

Method: Sinking Fund: $d = (P-F) (a/F, i\%, N)$

For $i = 15\%$, $N = 10$ years; $P = 622$; $F = 62$ (10%)

$B1 = (622 - 62) (0.0493) = \text{Rp. } 27.6$ million

2. Depreciation of constructional parts.

For $i = 15\%$, $N = 20$ years; $P = 748$; $F = 75$

$B2 = (748 - 75) (0.0098) = \text{Rp. } 6.6$ million.

3. Depreciation of special parts.

For $i = 15\%$; $N = 15$ years; $P = 80$; $F = 80$

$B3 = (80 - 8) (0.1483) = \text{Rp. } 10.6$ million

Total $B1 + B2 + B3 = \text{Rp. } 44.8$ million/yearas.

Table 3. Investments of the project in 1989.

Tabel 3. Investasi proyek pada tahun 1989.

	Million (Juta) Rp.
+ Solid State Fermentator (1400 m ³ a 0.4)	560
- Conveying and mixing (200 ton a 0.5)	100
+ Gas holder (1400 m ³ a 0.05)	70
- Generator (900 kw a 0.50)	450
- Chopper (55 ton a 0.8)	45
+ Substrate storage tank (55 ton a 0.70)	38
+ Humatex storage tank (15 ton a 0.70)	10
+ Piping and connections (200 m a 0.1)	20
- Pumping (20 ton a 0.2)	5
- Building (250 m ² a 0.2)	50
++ Plastic sealing machine (packaging) and sewing	10
- Press machine (15 ton a 1.5)	22
++ Control panels and computerization	20
++ Administrative accessories	20
++ Truck	30
T o t a l	1450

C. Production Cost**1. Fixed Cost**

Wages:

	Million Rp/y
- 1 Manager Rp. 500.000/month	6.0
- 1 Administrative Rp. 250.000/month	3.0
- 1 Insurance 10% (Of total wages)	4.0
	<hr/>
Total C_1	13.0
	<hr/>

2. Variable cost.

	Million Rp/y
- 3 Technicians a Rp. 10.000/d	10.8
- 8 Handlabourers a Rp. 6.000/d	17.3
- 1 Truck dirver a Rp. 10.000/d	3.6
- 1 Chemist for quality control	5.0
- Packaging : 57600 pieces of 50 kg each, a Rp. 250	14.4
- Gasoline for truck 50 l/d	3.8
- Administrative costs	5.0
- Contingencies 1%/total production cost	1.0
	<hr/>
Total C_2	60.9
	<hr/>

Total production cost $C_1 + C_2 = \text{Rp. } 73.9$ million.

D. Annual expenes

Depreciation + annual production costs:

$44.8 + 73.9 = \text{Rp. } 118.7$ million

E. Annul Revenues

- Electricity:		
6881 Kwh/d x 360 x Rp. 100	=	Rp. 247.7 million
- Humotex :		
8000 kg (90% DM) x 360 x Rp. 100	=	Rp. 288.0 million
		<hr/>
Total E.		Rp. 535.7 million

F. Project evaluation

1. Present worth method (PW)

	Present worth
	<hr/>
- Annual revenues Rp. 535.7 million (P/A, 15%, 20)	3353.1
- Salvage value (P/F, 15%, 20)	
Mechanical parts	15.3
Construction parts	4.6
Special parts	3.8
	<hr/>
	Rp. 3376.7 million
- Annual disbursement Investment 1450.0	
- Annual expenses (P/A, 15%, 20) 742.9	
	<hr/>
	Rp. 2192.9 million

Net present worth Rp. 1183.8 million

Since the net present worth is > 0 , the project is justified.

2. Benefit-cost ratio (B/C ratio)

$$B/C \text{ ratio} = \frac{B - (O + M)}{CR}$$

where $CR = (P-F) (A/P, 1\%, N) + F (1\%)$

CR (Capital recovery):

$$(1450 - (250.8 + 75 + 65.1)) 0.1598 + 390.9 (0.15) = 169.2 + 58.64 = 227.9$$

$$B/C \text{ ratio} : \frac{535.7 - 118.7}{227.9} = \frac{417}{227.9} = 1.83$$

The project is justified since the B/C ratio > 1.

3. The internal ratio of return (IRR)

$$IRR = \sum_{k=0}^N (R_k (P/F, i\%, k) - D_k (P/F, i\%, K)) = 0$$

$$-1450 + (535.7 - 118.7)(P/A, i\%, 20) + 390.9 (P/F, i\%, 20)i\%$$

$$\text{for } i = 10\% = -1450 + 417 (8.5136) + 390.0$$

$$(0.1486 + 2158.3)$$

$$i = 50\% = -1450 + 417 (1.99) + 390.9(0) = -620.17$$

$$\frac{50\% - 10\%}{1\% - 10\%} = \frac{-620.17}{2158.3 - (0620.17)}$$

$$\frac{987.9}{2158.3 - (-620.17)} = \frac{987.9}{2158.3}$$

$$i\% = 10\% + \frac{987.9}{2158.3 - (-620.17)} \times (50-10) = 10\% + (0.78 \times 40) = 41.2\%$$

G. Break even analyses

By grouping annual expenses into fixed costs and variable cost, the Break Even Point (BEP) can be calculated (at 15% interest):

Fixed cost (FC) : 13 + 44.8 = Rp. 59.8 million

Variable costs (VC) : Rp. 73.9 million

$$BEP = \frac{FC \times Sales}{Sales \times VC} \quad BEP = \frac{57.8 \times 535.7}{535.7 - 73.9} = 67.02$$

The BEP is situated at sales level of Electricity (46%):

Rp. 30.8 million = 883 KWh/d

Humotex (54%) : Rp. 36.2 million = 1.04 ton/d.

IV. DISCUSSION

Conversion of Empty Fruit Bunch (EFB) and Pericarp (P) from 2000 ha of oil palm estates by means of the Dranco process can give several advantages compared to direct burning:

- This process can produce either biogas or electricity while both are a high quality energy.
- Since the EFB and P are wet (25% DM) the direct burning system will lose lots of energy to vaporize the water, while the Dranco process can give high efficiency of conversion.

The electricity produced by the Dranco generator can be consumed either by the factory or the village people. Indeed, Martin (1981) estimated that about 400 kw of electricity is required per ha of housing area and service.

De Baere et al. (1987) stated that the quality of humotex produced from the organic fraction of municipal solid wastes is considerably different from that of conventional compost produced by means of an aerobic process. The humotex from Dranco process has a carbon to nitrogen ratio of 12 to 15, indicating a high degree of stability. For aerobic compost, this ratio varies from 10 to 30 depending on the maturity and the kind of material. The oxygen consumption is less than that of aerobic compost which leaves the reactor equivalent to that aerobic compost which has been cured during a period of minimum 4 to 6 months. Hygienic analysis of humotex indicates that fecal bacteria are almost completely absent. This high hygienic quality is also in sharp contrast with compost produced by means of conventional aerobic composting. In practice, humotex can be applied for the fertilization of the oil palm plantations, of rice fields, of horticultural crops, or for Forest Plant Estates which is projected to 6.2 million ha in Indonesia.

Other solid organic waste materials such as the leaves of oil palm trees after pruning could also be digested. Potential biogas production from 2000 ha plantations are estimated as follows:

$$2000 \text{ ha (2.8 ton DM/ha}^*) \times 0.3 \times 1.33 \times 0.35 \text{ m}^3 \text{ CH}_4/\text{kg COD} \\ \times 100/65 \times 1/365 = 3296 \text{ m}^3/\text{d}$$

*) Martin, 1981.

If the biogas is converted to electricity it will produce about 5211 KWh/d.

Conversion of the leaves to biogas will shorten their humification period. Normally by the SSF process, the humification is finished in 20 - 25 days. Recent findings by Sudradjat (1990) shows that the press liquor can be used as a high quality soil conditioner as well as hydroponic liquor. When the Dranco residue is pressed it can also be transformed to a very strong briquette without heat nor gule treatment is required.

V. CONCLUSIONS AND RECOMENDATION

1. This study focussed on 2000 ha of oil palm plantation. The Empty Fruit Bunch (EFB) and Pericarp (P) are estimated to be 14.5 ton DM, equal to 52.1 ton at 28% DM content.
2. By the Dry Anaerobic Conversion (Dranco) process, the substrates can produced biogas 4500 m³/d or 12700 m³ CH₄ equivalent to 94500 MJ/d. The latter could yield 7662 KWh electricity per day. The net electricity production is 6881 KWh/d.
3. The total investment of the project is estimated at Rp. 1450 million (1989).

4. Economic evaluation shows the following data.

	(million Rp.)
Annual expanses	118.7
Annual revenues	535.7
Present worth	1183.8
B/C ratio	1.83
I R R	41.2 %
BEP electricity	883 KWh/d
BEP humotex	1.4 ton/d.

5. Other organic wastes from plantation and factory for instance the leaves from pruning could also be used as substarte for producing biogas or electricity. Fro an acreage of 2000 ha oil plam estate roughly 5211 KWh/d electricity could possible be produced from the leaves.
6. In view of the potential benefits, both in the area of energy recovery and organic matter recycling, a more detail investigation in this field are urgently need-ed.
