ABSTRAK

During EFBO's delignification and acidic hydrolysis process, not all of lignocellulotic materials can be converted into monomer source. Handling of the by-product was carried out using mixed culture of cattle's rumen juice in anaerobic condition. The best result of the handling on the ratio of delignification medium by-product:hydrolysis:buffer solvent was 1:1:1 (w/v/v). Degradation of the liquid mixrure on a 3 litre bioreactor during eleven days decreased COD percentage of 69,68% and and biogas product of 5120 millilitres. Kinetic parameters of rumen microorganism on the liquid mixture resulted that saw rate of product forming on substrate ($Y_p/s = 0.14 \text{ ml\% NDF}$), biomass growth rate on substrate ($Y_x/s = 0.60 \text{ colony/ml\% NDF}$), specific maximum growth rate ($f_m = 0.81/\text{day}$), gas volume at time the substrate fully degraded ($V_f = 5190.60 \text{ ml}$), maximum gas forming rate (was $0.15 \text{ ml\% NDF/day}$), inflection time of gas forming/half time when gas forming was on the lag phase ($I = 0.9 \text{ day}$).
